Connecting TCAD To Tapeout

A Journal for Circuit Simulation and SPICE Modeling Engineers

IBIS Models Now Supported in SmartSpice

1. Introduction

The Input/output Buffer Information Specification (IBIS) is a standard for electronic behavioral models based on I/V and V/T curve data. It is being developed by the IBIS Open Forum, which is affiliated with the Electronics Industry Alliance (EIA). These models are suitable for high-speed designs of digital systems to evaluate Signal Integrity issues (deformation of electronic signals, cross-talk, power/ground bounce, transmission lines...) on printed circuit boards (PCBs).

The IBIS standard offers a way to provide fast and accurate models of I/O buffers without divulging any proprietary technology process. As it protects IP, it is now widely used by semiconductor vendors as a replacement for SPICE netlists. The IBIS standard specifies only what kind of information is provided, how this information is presented in ASCII files and how some data are derived from measurements or simulations. How these data are used and processed by a simulator is not part of the standard. The purpose of this documentation is to present the IBIS model support in *SmartSpice*.

The reader who is not familiar with the IBIS standard or would like to learn more about IBIS may refer to the Web site of the IBIS Open Forum at "<http://www.eigroup.org/ibis>" where numerous documents are available for download, including introductions, slide shows, articles and complete specifications (from the initial v1.0 to the latest v4.1 of January 2004).

2. IBIS Buffer Equivalent Circuit

A buffer is implemented as a new element in *SmartSpice*. Even though different types of buffers are available to cover a wide range of functions and technologies, they are all based on the same equivalent circuit, which is shown on Figure 1.

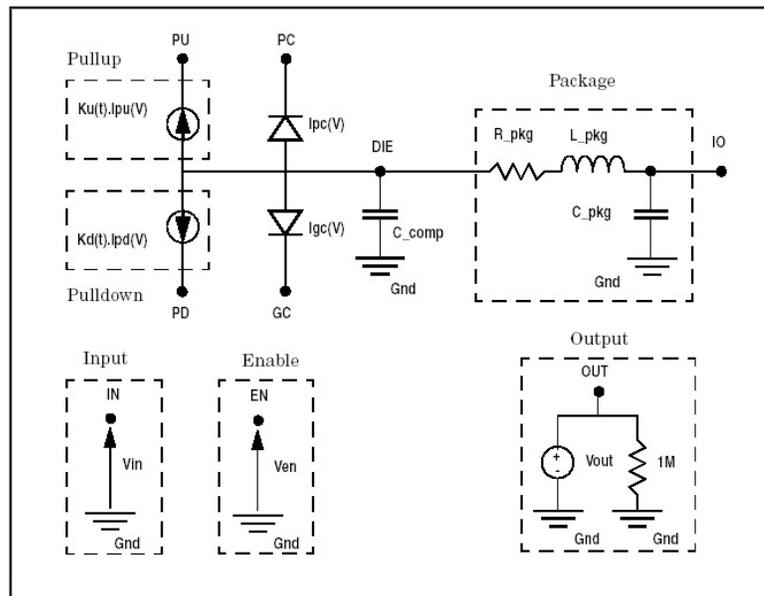

Figure1. IBIS Buffer General Circuit Diagram

Several elements and terminals are optional depending on the buffer type: Input (node IN) and Enable (node EN) high-impedance inputs, Output (node OUT) voltage source and conductance, Pullup/Pulldown (nodes PU/PD) Voltage-Controlled Voltage Sources (VCVS). Only Input/Output buffers have all elements and all terminals available. The number of terminals and the description of the equivalent circuit are given in Table 1 for all buffers currently supported in *SmartSpice*.

Table 1. Description of the equivalent circuit for all buffer types

The Gnd node corresponds to the SPICE ground node, also called node 0. All connections to Gnd are internal (C_comp, Vout...) and so this node is not available as a terminal. The die capacitance C_comp specified in IBIS models is usually connected between IO node and ground. However, if die capacitances C_comp_pc, C_comp_gc, C_comp_pu and C_comp_pd are specified in the IBIS model instead of C_comp, these four capacitances are connected between IO and PC, GC, PU and PD nodes, respectively.

PC/PU and GC/PD terminals are usually supposed to connect to power and ground rails, respectively. By default they are connected to internal voltage sources (not shown on the circuit diagram) and should not be connected to any other elements in the netlist (especially voltage sources). However the instance parameter **power** may be used to allow connections to external elements or power supplies.

Series and Series_switch buffers are currently not supported in *SmartSpice*. Terminator buffers also account for extra parameters corresponding to passive elements. These elements are not shown on the figure above. The complete equivalent circuit for terminators is given below with the information specific to terminators.

Optional Package Circuitry

Usually, buffers correspond to [Model] descriptions in IBIS files, which do not include package parasitics. The corresponding RLC elements may be added manually in the netlist using the values specified via [Package] or [Pin] keywords in IBIS files. However *SmartSpice* offers a simple alternative to automatically account for

this information without adding any external elements in the netlist. The optional package circuitry is internally created between IO terminal and DIE internal node when the instance parameters component and/or pin are specified on the device line. If component and pin are not specified, DIE and IO nodes are connected together to ensure compatibility with other simulators.

3. IBIS Buffer Device Line

Using buffers in *SmartSpice* is identical to using other elements like passive or semiconductor devices. The general syntax of a buffer statement is given by:

```
Bname term1 term2 term3 [term4 [term5 [term6
    [term7 [term8]]]]]
+ file = 'filename'
+ [model = 'modelname'] [component='componentname'
    [pin='pinname']]
+ [typ = {typ|min|max|fast|slow}]
+ [power = {on|off}]
+ [interpol = {1|2}]
+ [buffer = {number|type}]
+ [ramp_rwf] = {0|1|2}
+ [ramp_fwf] = {0|1|2}
+ [fwf_tune = value] [rwf_tune = value]
+ [c_comp_pc = value]
+ [c_comp_gc = value]
+ [c_comp_pu = value]
+ [c_comp_pd = value]
```

Device Naming Convention

The buffer element name must begin with B followed by optional alphanumeric characters.

Terminals

The number and the order of terminals specified on the device line are type-dependent:

- B_input PC GC IO OUT** (Input and Input_ECL)
- B_output PU PD IO IN [PC [GC]]** (Output, Open_drain, Open_sink, Open_source)
- B_three_state PU PD IO IN EN [PC [GC]]** (Three_state)
- B_input_output PU PD IO IN EN OUT [PC [GC]]** (Input_output, IO_open_drain, IO_open_sink and IO_open_source)
- B_output_ecl PU IO IN [PC [GC]]** (Output_ecl)
- B_io_ecl PU IO IN EN OUT [PC [GC]]** (IO_ecl)
- B_three_state PU IO IN EN [PC [GC]]** (Three_state_ecl)
- B_terminator PC GC IO** (Terminator)

Open_drain, IO_open_drain, Open_sink and IO_open_sink buffers have no pullup circuitry but PU terminal must be specified even though not connected to internal elements. Open_source and IO_open_source buffers have no pulldown circuitry but PD terminal must be specified even though not connected to internal elements. Output_ecl, Three_state_ecl and IO_ecl buffers have pullup and pulldown circuitry but no PD terminal because this latter node is internally connected to PU node.

Required Parameters

Specifying **file** parameter is required to define the location of the IBIS file containing the IBIS model description for this buffer. In *SmartSpice* this parameter is also used to decide if a B statement corresponds to a MESFET device or to an IBIS buffer. See Backward Compatibility paragraph below for further details.

In order to find the [Model] section in IBIS file it is also necessary to properly set model parameter. However if **component** and **pin** are given, **model** becomes optional. According to IBIS specifications, a valid pin description always contains the name of the associated model, which is used in *SmartSpice* as the default value of **model**.

- 'filename' is case-sensitive and must correspond either to the absolute path to the IBIS file or the relative path. For this latter case, IBIS files are searched from the directory where the simulator run, from the directory of the netlist containing the corresponding B-statement (which may be different from the current working directory) and from the paths specified via the option '**d_ibis**'. For convenience, the characters '\ ' and '/' are valid path delimiters in **file** and **d_ibis** arguments, regardless of the operating system.

- 'modelname', 'componentname' and 'pinname' are case-sensitive and must match one of the [Model], [Component] and [Pin] names defined in the IBIS file.

Optional Parameters

component and **pin** are used to account for package parasitics. If **component** is specified, *SmartSpice* first checks whether a [Component] description named '**componentname**' exists in the IBIS file, then gets the values of R_pkg, L_pkg and C_pkg from the corresponding [Package] description. R_pkg, L_pkg and C_pkg sub-parameters correspond to ranges in IBIS files, so the values used for the simulation also depend on the value of **typ**. If **pin** is also specified, *SmartSpice* checks whether a pin named '**pinname**' exists in the [Pin] list associated to the selected component. The first column of a [Pin] list contains pin names. A [Pin] list is a sub-parameter of a [Component] description in IBIS files. Consequently **pin** should not be specified if **component** is missing on the device line or if '**componentname**' does not match a valid [Component] name. If the optional parameters R_pin, L_pin and C_pin are available for the selected pin, these values override the default package values R_pkg, L_pkg and C_pkg, respectively. For this case, R_pin, L_pin and C_pin do not correspond to ranges and so are not dependent on the value of **typ**.

typ must be set to select what column of all IBIS data will be used during the simulation: TYP (default), MIN, MAX, SLOW or FAST. If FAST or SLOW are specified, the column MIN or MAX is selected depending on the IBIS parameter as defined in table 2. This is especially useful for best case / worst case analysis. If min or max values are not available in the IBIS model for a given parameter, typ values are used.

power is used to select how the buffer is powered via PC, GC, PU and PD nodes (if these latter nodes exist for the given buffer type).

- If **power** is set to 'on' (default), these nodes are internally connected to voltage sources whose values are taken from the IBIS parameters: [POWER Clamp Reference], [GND Clamp Reference], [Pullup Reference], [Pulldown Reference] (or [Voltage Range] if preceding parameters are missing). For this case, terminal names specified on the element card may be useful to print out the voltage values if needed.
- If power is set to 'off', internal voltage sources are not created and PC, GC, PU and PD nodes must connect to external voltage sources either directly or through passive devices like RLC networks or transmission lines.

interpol is the interpolation method selector.

- If **interpol** is set to 1 (default), I/V curves are interpolated using linear interpolation.
- If **interpol** is set to 2, quadratic bi-spline interpolation is used. This latter method is usually not recommended and useless anyway if IBIS data are accurate.

IBIS Parameter/Data	Fast	Slow
C_comp	min	max
C_comp_pc	min	max

L_pkg	min	max
C_pkg	min	max

Table 2. Min/Max combinations for Slow/Fast conditions

buffer is used to specify the type of the buffer. This value overrides the corresponding IBIS parameter *Model_type*. It is usually not recommended to specify a different value. Integer values are allowed to select a buffer. The correspondence with literal names is given in table 1.

ramp_fwf and **ramp_rwf** selectors allow the user to choose the calculation method of multipliers $K_u(t)$ and $K_d(t)$. These parameters are totally independent and may have different values.

- If **ramp_fwf** (or **ramp_rwf**) is set to 0 (default), only the ramp data is used to derive multipliers for the falling (or rising) transition
- If **ramp_fwf** (or **ramp_rwf**) is set to 1, the first falling (or rising) waveform table available in IBIS model is used to derive corresponding multipliers
- If **ramp_fwf** (or **ramp_rwf**) is set to 2, the first two falling (or rising) waveform tables available in IBIS model are used to derive corresponding multipliers

These latter option is highly recommended to get accurate results in transient analysis. However, if the required data are not available in IBIS model, the value of **ramp_fwf** (or **ramp_rwf**) is decremented and a warning message is issued. For example, if **ramp_fwf** = 2 and only one waveform table is given, then **ramp_fwf** is set to 1, if **ramp_fwf** = 1 and only ramp data are given, then **ramp_fwf** is set to 0.

fwf_tune and **rwf_tune** factors are control parameters for **ramp_fwf** = 0, 1 and **ramp_rwf** = 0, 1 algorithms, respectively. When only ramp data or one waveform is available, it is necessary to impose an additional condition to compute multipliers. Usually it is assumed that $K_u(t)+K_d(t)=1$, which was demonstrated to be not realistic because the circuitry that goes from ON to OFF undergoes this transition faster than the circuitry that goes from OFF to ON.

By setting **fwf_tune** or **rwf_tune** to a value between 0 and 1 (default 0.1), it is possible to get more accurate transitions by using the following assumption: if ΔT is the duration of a complete transition, the multiplier $K(t)$ corresponding to the circuitry that goes from ON to OFF decreases linearly from 1 to 0 between $t=0$ and $t=fwf_tune * \Delta T$ (or $t=rwf_tune * \Delta T$ depending on the transition). Thus, the other multiplier is uniquely determined from an IBIS ramp or one IBIS waveform. The multiplier computation methods are described in articles (1, 2).

C_comp_pc, **C_comp_gc**, **C_comp_pu** and **C_comp_pd** are dimensionless die capacitance partitioning factors. They do not override the IBIS parameters with the same names, which correspond to actual die capacitances. If these latter capacitances are specified in the IBIS model, the dimensionless factors are useless and ignored if given on the element card. If only **C_comp** is available in the IBIS model, it may be desirable to split it into several parts for simulating power/ ground bounce. This is achieved by specifying the fractions of **C_comp** connected between IO node and PC, GC, PU, PD nodes. If given, the values of instance parameters **C_comp_pc**, **C_comp_gc**, **C_comp_pu** and **C_comp_pd** should be between 0 (default) and 1. It is also expected that their sum equals 1.

4. Buffer Logical State

The logical state of a buffer is controlled by the voltage of IO, IN and/or EN nodes relative to ground and noted V_{io} , V_{in} and V_{en} , respectively.

For buffers with no controlling signals (no IN or EN nodes), the state is a function of V_{io} , the IBIS parameters V_{in_l} , V_{in_h} (thresholds), Polarity and the previous state if any.

If Polarity=Non-Inverting

- Initially (t=0 in transient analysis or first computed point of a DC sweep), state is set to LOW if $V_{io} < (V_{in_h} + V_{in_l})/2$ or to HIGH in the opposite case.
- If state=HIGH then it goes to LOW only if $V_{io} < V_{in_l}$.
- If state=LOW then it goes to HIGH only if $V_{io} > V_{in_h}$.

else Polarity=Inverting

- Initially (t=0 in transient analysis or first computed point of a DC sweep), state is set to LOW if $V_{io} > (V_{in_h} + V_{in_l})/2$ or to HIGH in the opposite case.
- If state=HIGH then it goes to LOW only if $V_{io} > V_{in_h}$.
- If state=LOW then it goes to HIGH only if $V_{io} < V_{in_l}$.

For buffers with only one controlling signal (IN node), the state is a function of V_{in} , the IBIS parameter: Polarity and the previous state if any. Here thresholds are constant built-in parameters.

If Polarity=Non-Inverting

- Initially (t=0 in transient analysis or first computed point of a DC sweep), state is set to HIGH if $V_{in} > 0.5$ or to LOW in the opposite case.
- If state=HIGH then it goes to LOW only if $V_{in} < 0.2$.
- If state=LOW then it goes to HIGH only if $V_{in} > 0.8$.

else Polarity=Inverting

- Initially (t=0 in transient analysis or first computed point of a DC sweep), state is set to HIGH if $V_{in} < 0.5$ or to LOW in the opposite case.
- If state=HIGH then it goes to LOW only if $V_{in} > 0.8$.
- If state=LOW then it goes to HIGH only if $V_{in} < 0.2$.

For buffers with two controlling signals (IN and EN nodes), the state is a function of V_{en} , V_{in} , V_{io} , the IBIS parameters: V_{in_l} , V_{in_h} (thresholds), Polarity, Enable and the previous state if any. The enable signal V_{en} supersedes the input signal V_{in} and is used to determine whether the buffer is in ENABLE or DISABLE state:

If Enable=Active-High

- Initially (t=0 in transient analysis or first computed point of a DC sweep), buffer is ENABLE if $V_{en} > 0.5$ or DISABLE in the opposite case.
- If buffer=ENABLE then it goes to DISABLE only if $V_{en} < 0.2$.
- If buffer=DISABLE then it goes to ENABLE only if $V_{en} > 0.8$.

else Enable=Active-Low

- Initially (t=0 in transient analysis or first computed point of a DC sweep), buffer is ENABLE if $V_{en} < 0.5$ or DISABLE in the opposite case.
- If buffer=ENABLE then it goes to DISABLE only if $V_{en} > 0.8$.
- If buffer=DISABLE then it goes to ENABLE only if $V_{en} < 0.2$.

If a buffer is ENABLE, the state is controlled by V_{in} according to the rules defined above for buffers with only one controlling signal (IN node).

If a buffer is DISABLE, there are two possible behaviors depending on the type:

- For buffers without output circuitry (no OUT node), the state is just locked till the buffer returns to ENABLE. Three-state buffers belong to this family.
- For buffers with output circuitry (OUT node), the state is controlled by V_{io} according to the rules defined above for the buffers with no controlling signals. Input-output buffers belong to this family.

The logical state can be printed out if the output circuitry (OUT node) is available:

- If state=HIGH then $V_{out}=1.0V$. If state=LOW then $V_{out}=0.0V$.
- OUT node can also connect to external elements, especially IN or EN nodes of other buffers. This nodes offer a simple way to create complex digital blocks in SPICE netlists.

5. Output Variables

The variables listed in table 3 can be printed out using the SmartSpice syntax `@B_name[variable_name]`:

Variable Name	Definition
ku	Pullup transient current multiplier
kd	Pulldown transient current multiplier
cio	Input/Output terminal current
cpc	Power Clamp terminal current
cgc	Ground Clamp terminal current
cpu	PullUp terminal current
cpd	PullDown terminal current
cin	Input terminal current
cen	Enable terminal current
cout	Output terminal current

Table 3. Buffer internal variables.

6. Terminator Buffers

A terminator is similar to an input buffer except that it has no internal logical state (no output terminal, Vinh and Vinl not required) and may include optional passive elements as shown on Figure 2.

Rpower, Rgnd, Rac and Cac sub-parameters correspond to ranges in IBIS files, so the values used for the simulation also depend on the value of typ. For 'fast' and 'slow' values, the column is chosen according to table 4. If a value is not available or is unrealistic (negative resistance or capacitance), the corresponding element is simply removed from the circuit. Cac must be set to a positive value otherwise the entire branch Rac/Cac is not created, even though Rac is set to a positive value.

IBIS Parameter/Data	Fast	Slow
Rpower	max	min
Rgnd	max	min
Rac	max	min
Cac	min	max

Table 4. Min/Max combinations for Slow/Fast conditions (terminator elements).

Like other buffer types, the optional package circuitry is internally created between IO terminal and DIE internal node when the instance parameters component and/or pin are specified.

7. IBIS-Related Options

GMIN/DCGMIN conductances are connected in parallel with PC and GC diodes and with PU and PD Voltage-Controlled Voltage Sources if they exist (type-dependent) to ensure better convergence of buffer devices in particular situations.

The option VZERO=2 can also be specified in netlists containing IBIS buffers. This may help to speed-up computation in some cases.

A new option **d_ibis** has been added to specify the location of .ibs files. Several paths can be specified. A .ibs file will be searched in all specified paths if the filename given on B statements is not an absolute path and is not found in the directory from which SmartSpice runs. This option is case-sensitive. For example:

```
.option d_ibis='/home/mylogin/myIbisModels'
```

d_ibis is also available as a variable and can be set in SmartSpice .ini files. For example:

```
set d_ibis = ( ./home/mylogin/myIbismodels )
```

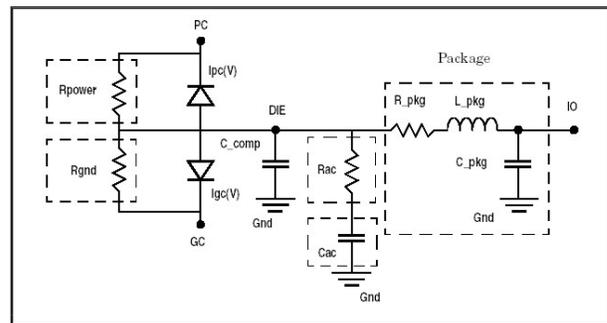

Figure2. Terminator Buffer Circuit Diagram.

8. Backward Compatibility

In previous releases of SmartSpice, B statements were only used to define instances of MESFET models (as an alias of Z). From now on, they may also be used to define IBIS buffers. When a B statement is encountered in a netlist, *SmartSpice* first checks whether the IBIS-specific parameter **file** is specified in the element card. As this parameter is required to create an IBIS buffer, *SmartSpice* creates a MESFET device if they are missing, so that backward compatibility is maintained.

9. Limitations

- Only DC, Transient and AC analysis are supported for IBIS buffers.
- Unlike other simulators, the IBIS Golden Parser is not incorporated into SmartSpice yet. As a consequence SmartSpice does not check the syntax of .ibs files and just issues a generic 'parse error' message if the syntax of an .ibs file is not in compliance with IBIS v3.2 specifications. To avoid such problems all .ibs files should be systematically verified with the Golden Parser, freely available as an executable on the IBIS Open Forum web site. If the Golden Parser reports warnings and errors, the .ibs file can probably not be used in SmartSpice netlists.
- The series and series switch buffers are still not supported.
- The capability for SmartSpice to use [Component] descriptions is under development.
